MEMOIR

OF

A GEOLOGICAL MAP OF ENGLAND;

TO WHICH IS ADDED, AN

ALPHABETICAL INDEX TO THE HILLS,

AND A

LIST OF THE HILLS

ARRANGED ACCORDING TO COUNTIES.

BY

GEORGE BELLAS GREENOUGH, F.R.S.

PRESIDENT OF THE GEOLOGICAL SOCIETY OF LONDON AT ITS ESTABLISHMENT
AND AT SUBSEQUENT PERIODS,
PRESIDENT OF THE ROYAL GEOGRAPHICAL SOCIETY OF LONDON, ETC.

SECOND EDITION.

LONDON:

SOLD AT THE APARTMENTS OF THE GEOLOGICAL SOCIETY,
SOMERSET HOUSE.

1840.

INTRODUCTORY MEMOIR.

I BEG leave to append to the new edition of my Geological Map of England and Wales the following brief explanation.

Of the six copper-plates upon which the old map was engraved, four and the lower portion of the fifth have been used again; the upper portion of the fifth and the entire sixth are new.

The southern sheets were drawn originally, in part at least, from the best documents, those of the Ordnance Survey: for the topography of the northern, good authorities are still wanting; the eastern sheet, if reconstructed, might be greatly improved, but the inaccuracies in it, geologically considered, are of little importance: for thus much of the map therefore new copper-plates might well be dispensed with; not so for the remainder. Of the physical features of Wales (and Siluria more especially) a rough sketch, such as was given in the first edition, would be wholly unsuited to the present state of our knowledge. To do justice to the great mass of information which we now possess of that part of the kingdom a detailed and scrupulously correct drawing is essential. Such a drawing the admirable maps which have recently issued from the Ordnance press have afforded me the opportunity of obtaining; and the result will I trust be approved not merely by professed geologists, but by all who feel an interest in the progress of art, more especially when exerted in furtherance of science.

The intermixture of good and bad materials in the same work is an imperfection which could not be avoided, and which it would therefore be unjust to censure and vain to regret.

Anachronisms must be tolerated for the same reason, since maps are founded on surveys, and surveying must always be a work of time. The roads represented upon the new plates only are modern; those on the old existed long ago, and the line of the greater number has in all probability been more or less altered and improved. I have left them, however, un-

Digitized by Google

touched, since, to rectify all would have been impracticable, and partial change would have only led to confusion. The Railroads have been added, but in a character so distinct that they cannot be mistaken.

Having always felt the close connexion which necessarily exists between the outward form of a country and its geological structure, I have made it a primary object to represent with distinctness and fidelity all undulations of the surface as far as I had the means of determining them, and the scale of the map would allow. The chains, ridges, and principal groups were laid down in the first instance from the masterly sketch of General Roy, and afterwards resolved into their constituent parts either by personal observation or a diligent and careful examination of country and district surveys. More than thirteen hundred heights are distinguished in the first edition and more than fifteen hundred in the present; their relative altitudes are shown, since they are shaded to scale: by the substitution of signs for names (a process characteristic of this map) this vast body of orological detail has been accommodated without crowding or confusion.

Equal attention has been paid to hydrography. The course of rivers and brooks has been drawn neither fancifully nor negligently, and in the new parts at least will be found minutely correct: the force with which the graver has been applied disengages these lines from all with which they might otherwise have been confounded, and not only shows more distinctly the hydrographical basins, but assists even in developing the shape of the intervening ground. The names of the smallest streams have been diligently sought and recorded; and those of rivers are generally inserted both at their mouths and at their forkings.

In the Table of Formations several changes have been made with a view to simplification, or to introduce subdivisions, or to comply with the prevailing taste of the day. The upper and lower members of the greensand, formerly united, are now separated by a streak of gault. The fullers'-earth and upper lias marl are separated from the other members of the Cotswold series and laid down according to the observations of the late Mr. William Smith, Professor Phillips, and Mr. Lonsdale. The new red sandstone group has been dissected after the manner of the Germans, and in Siluria the divisions first established by Mr. Murchison have broken up the unity of the *quondam* greywacke formation.

In determining the Boundaries of the strata, I have added to my own personal experience that of other competent observers, and assiduously collected information of all kinds wherever it was to be found. Among the most valuable communications which I have received and profited by,

Digitized by Google

I have much pleasure in acknowledging those of Mr. De la Beche, Mr. Jukes, Mr. Logan, Mr. McLachlin, Mr. Milne, Mr. Murchison, Professor Sedgwick, Mr. Sopwith, Mr. Strickland, Mr. Taylor, Mr. N. Wood, and more especially Mr. Lonsdale. Had I not been obliged to abandon for the present a favourite object, that of classing and subdividing the several coal-fields, I should have noticed the liberal contributions of other individuals, whose names are now reluctantly passed over in silence. The green sand has been laid down according to the views, and partly under the superintendence of Dr. Fitton; and I have profited on many occasions by the labours of Professor Phillips in the northern counties.

On comparing the Geological Boundaries of the old map with those of the new, I hope to be excused for indulging some slight feeling of self-congratulation. When I call to mind the rigid scrutiny which almost every part of the kingdom has undergone within the last twenty years, together with the increased facilities of investigation, (distinct sections being now exposed in places which formerly appeared doomed to endless obscurity,) I cannot but be gratified to observe that the geological errors of the first edition are far less grave and less numerous than under such circumstances might reasonably have been apprehended; the principal of these errors, and the only ones I think which here require to be specified, will be found in Leicestershire and in the Western Counties. The false colouring in Leicestershire is of small extent, and arose from accidental carelessness; that in Devonshire and Cornwall from imperfect information. I need not remind the Society of the animated discussions which have taken place respecting the true structure of these counties during the last three years, and which have not even yet, it appears, reached their termination. The way in which I have treated this *vexata quæstio* in the new edition of my map may perhaps excite some interest; at all events it requires some explanation*.

The lower deposits of these counties, as formerly represented, consist either of Clay-slate with cross courses of elvan, or Greywacke slate, with its usual suite of greywacke, transition limestone, and culm. In place of these we have now presented to us Old Red Sandstone with subordinate bands of limestone, Mountain limestone, and Coal.

* Between my representation of the Cornish and Devonian rocks and that put forth in a small skeleton map of England by Prof. Sedgwick and Mr. Murchison in the course of last year, the resemblance is so obvious, that it is necessary for me to notice only the difference. The object in their map was to disconnect the Devonian from the older Transition beds; in mine to connect them. Hence the colour they have chosen presents a contrast to that of the lower killas or Cambrian system; that which I have chosen presents an attempt, however imperfect, at approximation.

The Devonian rocks I have always believed, and still believe to agree with those of the Harz; and if either at the date of the publication of their map, or subsequently, on more extended experience, and after more mature consideration, Messrs. Murchison and Sedgwick have arrived at the conclusion that the Devonian system and the Harz system are one and the same, they have only confirmed, by the high authority of their names, the correctness of a doctrine laid down in the former edition of my map, as well as the present.

Digitized by Google

This change will no doubt appear uncalled for, when I state that, in the metalliferous rocks of Tavistock-tunnel, Redruth, and St. Agnes, &c., I still recognise all the characters of Wernerian Clay-slate, and in the tract formerly coloured as Greywacke all the characters of that group as it exists in the Harz, the district where the term originated, and to which therefore, in cases of doubt, we are bound to appeal in *dernier ressort*, as the true and undoubted type of the greywacke formation.

Hence it becomes necessary to observe, first, that the characters which Werner assigned to Clay-slate are not confined to it; and secondly, that the Old Red Sandstone has obtained admission into this part of my map only by a sacrifice of its independence, and upon condition of taking rank there only as an *integrant member of the Greywacke formation.*

The term Greywacke, if employed in a *mineralogical* sense may safely continue to be used for the purpose of designating that granular compound of semicrystalline fragments cemented by slate-clay, which is found in rocks of every epoch, in the Grampians, in Cardiganshire, in the Tarentaise, along the whole range of the Alps, the Carpacks, the Apennines, &c.; in a *geological* sense, if employed at all, it should be strictly confined in its application to the Hercynian system and its equivalents.

But what is the Greywacke of the Harz? have the relations of that deposit been sufficiently examined to enable us to reply satisfactorily to the question? Is it not probable that the age of the Harz rocks will soon become a subject of controversy? and if so, in what sense should the term be employed *pendente lite?*

Our language is rich enough to enable us to dispense with a word which has long since been objected to with reason as being harsh in utterance as well as uncertain in signification, and therefore I think we ought, as geologists, to abstain from all further use of it. The phrase "Old Red Sandstone" is equally superfluous. Therefore I venture to apply the designation of *Upper Killas* to the series of beds above the Silurian, and that of *Lower Killas* to the series below the Silurian.

To the terms Devonian and Cambrian, by which it has been proposed by Professor Sedgwick and Mr. Murchison to indicate what is here named upper and lower Killas, I entertain the following objections:—

1. If by Devonian system, we are to understand only a part of the rocks of Devon, we lose the only name we have whereby to designate the whole.

2. If we apply this name to denote the agreement of the Devon rocks with those of Herefordshire and other midland counties, we lose the only name we have to denote, (what is equally worthy of being denoted,) their disagreement.

Digitized by Google

3. The expression "Devonian system" is just as applicable to the culmiferous beds of Devon as to the beds beneath them.

4. The name of an English county is not a proper designation for an extensive European range*.

5. The title Cambrian system, according to its natural and obvious signification, should include all the rocks of the principality,—among others the very system to which it is opposed, the Silurian.

Mr. Bakewell, after denying that there is any other distinction between old red sandstone and greywacke than the accidental one of colour, adds: "Until English geologists shall renounce their prejudices and place "the old red sandstone and mountain limestone in the transition class as "greywacke and transition limestone, every attempt will be vain to iden-"tify this part of the geology of England with that of the continent." In this opinion I concur. The old red sandstone has not been discovered in any part of the continent, only because our type of the group was unfortunately taken from a district where it throws off its natural character and appears in disguise. Had the type been taken from Devonshire, it is no longer doubtful that the old red sandstone would have been recognised long since over a great part of Europe.

The *true* characters of the Formation are nowhere better laid down than in the System of Geology of the late Dr. McCulloch. His ideas were derived mainly from his experience in Scotland, but they are equally just when applied to the west of England.

"The red colour," he says, "is not an invariable characteristic of this "rock: in its Depth it presents an infinite variety, the Mass of strata "being either originally thin, or else attenuated in some places till it dis-"appears, while in others it amounts to many hundred yards in thickness.* * "* * * The Dimensions of the Individual Strata are also various; the con-"glomerate beds being commonly the thickest, as the fine ones are the re-"verse; though the former are sometimes divided into distinct strata by finer "sandstones. When not thus separated (as is most common) they often "attain the depth of a hundred feet or upwards without a division; while "the fine sandstones vary from a few yards to as many feet, and even to "less than an inch in thickness; when they consequently assume a schis-"tose character. In these cases, the divisions of the beds sometimes re-"sult from a change of texture or composition; at others, from the inter-

* If this objection be overruled, the title most in keeping with Silurian nomenclature, and at the same time free from the other objections which are here made, would be Dumnonian.

Digitized by Google

" vention of mica, or clays of different characters, or shales, or argillo-
" calcareous compounds.

" Viewing this Sandstone as a single geological deposit or group, ex-
" tending from the primary strata to the mountain limestone, it includes
" other substances inferior in quantity, and irregular in their occurrence.
" The chief of these are Argillaceous Schists, though considered as shales
" under the adopted classification. These are sometimes *undistinguish-*
" *able from the Primary greywacke schists*, when separated from their
" connexions; while, at others, they are mixed with the ordinary materials
" of the Sandstones, so as to present transitions into it. In other cases,
" again, they are *as fine and compact as the Primary Slates*, occasionally
" resembling even *the green chloritic varieties*. Lastly, beds resembling
" the ordinary Shales of the upper strata, occur also in this deposit; being
" simply argillaceous or argillo-calcareous, or so charged with iron as to
" be red or yellow, and thus finally passing into argillaceous ironstone.
" *Beds of Limestone are* also sometimes contained in the Red Sandstone,
" *though seldom extensive*, and rather forming *irregular masses* or limited
" strata *than continuous alternations*. At times they are mixed with the
" fragments of the surrounding conglomerate, at others divided by laminæ
" of shale, and contaminated with clay, siliceous matter, and oxides of
" iron; occasionally also containing organic remains. *Coal* also occurs
" in it, though rarely, and seldom in any quantity; yet so as to be occa-
" sionally wrought in a limited manner in Scotland.

" I must now point it out as a general fact in my experience, that
" wherever this sandstone is highly indurated, its Shales, whether fine or
" coarse, are identical with the Primary schists, and that the argillaceous
" beds among the softer ones resemble the shales and clays of the upper
" sandstones. And it is a connected fact, leading to a similar inference,
" that the *Indurated beds occur in the vicinity of the Primary rocks*, and
" more particularly in that of gneiss or the other older strata, as the less
" Compact ones are found in the reverse situations."

The above description characterizes, in every important particular, the Killas and Shillot beds of Devonshire and Cornwall. I consider myself, therefore, fully entitled, on lithological evidence, to assign to these rocks, that place in the general series which they occupy in the present map.

The evidence to be derived from Palæontology, though incomplete, points distinctly to the same conclusion. It is true, that the fossils hitherto collected in the western counties, do not correspond with those of Here-

Digitized by Google

fordshire, nor are the fossils of the northern coast of Devonshire and Cornwall capable of identification with those of the south; these discrepancies however may be fairly attributed in great measure to the different conditions under which the beds were deposited, and the inconstancy of their mineral character; and it should be borne in mind that all the lists of fossils are still very far from complete.

In the Devonian Red Sandstone (its subordinates included) we find numerous shells identical, or nearly identical, with those of the Mountain limestone; and numerous corals identical, or nearly identical, with those of the Silurian limestones; they contain, moreover, very striking genera and species of shells hitherto undiscovered in either of these or in any other formation; they contain also in North Devon traces of fossil plants, differing, I believe, from those of true coal, and agreeing apparently with those found in old red sandstone at Arbroath in Scotland.

Resting conformably upon these beds, we find near Barnstaple and Swimbridge others of *earthy sooty limestone*, not unlike calp; irregular patches of this limestone may be traced eastwards to Holcomb Rogus and West Leigh, when it changes its character, throws off its impurities, and assimilates to the limestones of Plymouth and Torbay: the dip of these beds is to the south, and being disposed in the shape of a trough, they rise up again with a contrary dip at Launceston and South Petherwin. For fossil contents, this limestone differs from all the others; and whether we regard the character of the genera where the species is uncertain, or of the species where it is determinable, we are warranted in considering it the representative of the true Mountain limestone. Goniatites and Posidonia, the most frequent shells, have not yet been discovered in any portion of the old red sandstone formation.

Under these circumstances, I cannot but think it highly probable that the Culm limestone of Barnstaple, &c. occupies the same place in the general series as that which in other countries forms the floor of our Coalfields; and this being admitted, it follows as a necessary consequence, that the superincumbent Shales, marked with vegetable impressions, are legitimate members of the great Carboniferous system.

If further evidence on this subject be required, there is still in reserve another argument with which Mr. Murchison has kindly supplied me, derived from his recent researches in Germany,—an argument of analogy.

The transverse sections in descending order from the well-known coalfield of Westphalia (notably in the zone between Hagen and Iserlohn), exhibit clearly a descending order from the productive coal strata through beds representing our millstone grit, and then through various schists and sandstones with minute plants resembling those of the culm measures of

Digitized by Google

Devon; next through bands of flag-limestone, undistinguishable from the black limestones of Barnstaple, and, like them, containing Posidonia and Goniatites, and associated with bands of flinty slate (the Kiesel-schiefer of the Germans). Passing to still lower strata of schists and psammites, other calcareous courses appear, including the great limestone of the tract, which contains the same fossils as the limestone of S. Devon; and finally, these are underlaid by greywacke and subordinate courses of limestone, which rise into the higher mountains of the region, and contain *Homalonoti*, *Pterineæ*, and other shells characteristic of the upper members of the Silurian system.

There is perhaps no department of geological mapping in which judgement and consideration are so requisite as in the choice and distribution of Colours. In purely Geographical Maps those Colours are most appropriate which are most pleasing, but the tints of a Geological Map speak to the mind as well as to the eye, and the relations of these to one another must convey clear and definite ideas of the mutual relations of the objects which they are employed to represent.

In the Choice of pigments to be employed, I have sought the most transparent; the most distinct; those least subject to fade by exposure to air, to light, or to damp; those which are most soluble; and those, of which the ingredients will not act chemically one upon another.

In the Distribution of pigments I have endeavoured to accommodate the colour of the pigment to that of the substance represented; to apply to substances mineralogically similar, similar tints, to substances mineralogically dissimilar, dissimilar tints; to place in juxtaposition those colours only which would either harmonize or contrast, as the occasion might require; to confine the more opake colours to those parts of the map which are least charged with engraving; to reserve the most formidable colours for the smaller spaces; to denote marked differences in adjoining rocks by strong opposition of hue; to avoid spottiness; and lastly, to apply the brightest colours to the centre, carrying them off by gradation towards the extremities. All these objects can rarely be attained in any case, but all were taken into consideration before the colouring of any portion was finally decided upon.

Success in colouring a map of this nature depends no less upon practice than principle. Arbitrary tints may safely be entrusted to a beginner, but where every colour is to convey a definite and precise idea, there is no longer any room left even for momentary inattention. Colours so appro-

Digitized by Google

priated must be laid on uniformly, or they deceive. If due allowance be not made for the difference of intensity which the same tint assumes, as it is wet or dry; for the difference of effect which the same tint will produce when placed in a juxtaposition with others; if pigments bearing the same name be not precisely of the same quality; the language we employ no longer accomplishes its purpose, and conveys to the mind only false impressions. Before the colouring can be deemed complete, the map must undergo the process which in the language of art is called "toning," not for the sake of effect, but of distinctness.

In tinting by hand a geological map, the temptation to inaccuracy is so constant and powerful; the difficulty of avoiding it so great; and the consequences resulting from it so fatal to the object in view; that the duty can never be entrusted safely, unless to artists of acknowledged skill and established character, nor even to them without subsequent revision; and these securities necessarily involve considerable expense. To obviate this objection, various attempts have been made, both here and on the Continent, to effect by machinery what at present is done by hand. Where slight inaccuracies are not likely to be noticed, as in figured papers used for the lining of rooms, or coarse, common maps, where the names and lines are few in number, and many of them already out of place, the pattern is obtained by the application of blocks or stamps, and the same process might with confidence be applied to finer work, but for the change of dimensions which the paper undergoes in drying. I have lately been informed (and I hope with truth) that this change may be counteracted.

The Application of Machinery to this purpose is one of the greatest desiderata in the department of geological mapping; and when once this is supplied, the only grave objection to the system of expression to which we have been so long accustomed, would be the inadequacy of colours to perform all the functions required of them. The most effectual remedy for this is a determination not to require of colours more than they can perform; so to diminish the Number of tints adopted, that small aberrations in the copy from the established tints of the original may not occasion confusion or lead memory into mistake; and to employ largely (as I have done sparingly) shaded grounds, to be tinted or not tinted as may be found expedient. This contrivance may be resorted to with advantage on very many occasions, and made subservient to a variety of purposes. Where the shade is produced by lines repeated at small intervals, we obtain a tint cheaper, purer, brighter, more constant and uniform, more durable and far less injurious to the engraving beneath, than any wash whatever. The Breadth, Depth, and mutual Distance of the lines being all capable of modification, a large series of such lines may be obtained vary-

Digitized by Google

ing from the faintest grey to absolute black, every one of which, from being neutral, must harmonize with whatever colour may happen to be its neighbour; the direction of the lines also may vary indefinitely, and if we choose to introduce into our scheme this new Element of Expression, we may at once confer upon every member of the series the power of representing an almost indefinite Number of Modifications; and this without the slightest risk of one being mistaken for another. Horizontal ruling, so far from doing injury to the plan-work, in all cases (where the idea of flatness is to be conveyed) greatly heightens its effect; when used *substantively*, I should recommend its employment in the first instance to represent clay or coal; vertical lines would be best appropriated perhaps to trap-rocks, interrupted lines to chalk, waved lines to slate. To express arenaceous beds we have a further resource in engraved dots, which I have used for denoting the Bagshot sand; the form of these dots again may be varied indefinitely. When engraved lines or dots are employed not as single tints, but as a ground for other tints, performing the function of *adjectives*, they have this great merit that they subdivide a formation without destroying its unity. I have availed myself of this expedient in laying down the beds of the Weald and of the Cotswolds.

The capricious employment of different tints by different authors to indicate the same object has often been complained of, and it has been proposed by way of remedy, that a list should be formed of formations, and that a set of uniforms should be agreed upon which they should always wear, and by which they might be everywhere recognised at a glance. This proposal, however, is upon the old system, not very easy of execution: first, because the number of substances to be distinguished varies indefinitely according to the nature and object of the several maps in which these uniforms are to be seen; secondly, because different minds frame different schemes of classification, and enlarge or diminish the groups as their own good pleasure or the nature of the countries represented may suggest; thirdly, because the same colour employed under different conditions would lead to very different optical results, being in perfect harmony when applied to one map, when applied to another, painfully discordant.

In illustration of this last remark, I may observe, that the tints employed in the present map are found by experience to accord well with the structure of Germany, but to be very ill adapted to that of Scotland.

Though the list of formations which we find in elementary books is not long, yet owing to the caprice either of nature herself or of her disciples, the number of divisions and subdivisions which require admission into geo-

Digitized by Google

logical maps, very constantly exceeds the number of tints which the most practised eye can discriminate; nor is it expedient under any circumstances or with any proviso that these tints should be repeated. To overcome the difficulty other contrivances have been resorted to, which have been attended, however, with very imperfect success. Coloured bars, and especially cross-bars, not only deface the physical features, but give additional trouble. The repetition of the same tints in different senses introduce confusion, which the annexation of Roman capitals, numerals, or other symbols can never effectually remove. Fortunately, the combination, here recommended, of colours with linear shadows affords a range of expression far greater than is likely to be required for any geological purposes; and I therefore indulge a hope, that if it be possible to dissolve the long-established connexion between many men and many minds, and if with a view to the furtherance of science, the members of this and similar societies will make common cause to effect an object, the importance of which well warrants the attempt, it will not be found difficult, by the judicious application of this simple contrivance, to give to the geological map maker the blessing of an easy, copious, elegant, precise, and *universal* language.

EXPLANATION of the SIGNS

Employed to denote

THE DIFFERENT HILLS,

Arranged according to

COUNTIES IN WHICH THEY ARE SITUATED.

Names distinguished by an Asterisk are engraved on the Map.

ENGLAND.

BEDFORDSHIRE.

a Hammer Hill
b Wilbury Hill
c Pegson Beacon
d Dunstable Downs
* Pollux Hill
* Luton Downs

BERKSHIRE.

a Badburrow Hill
b Faringdon Clump
c White Horse Hill
* Cooper's Hill
* Fox Comb Hill
* Seven Barrows
* Wittenham Hills
* Coldbury Hill
* Cuckhamsley Hills

BUCKINGHAMSHIRE.

a Bow Brick Hill
b Halton Hill
c Muzzle Hill
* Waddon Chase
* Iver Heath

CAMBRIDGESHIRE.

* Madingley Hill
* Gogmagog Hills

CHESHIRE.

a Heswell Hill
b Overton Hill
c Utkinson Hill
d Luddington Hill
e Alderley Edge
* Featherbed Moss
* Beeston Castle
* Peckforton Hills
* Delamere Forest

CORNWALL.
